

# Answer Sheet to Complex Geometry

Zhan Fangrong

1. Let  $\Omega \subset \mathbb{C}^n$  be a connected domain. Let  $f \in \mathcal{O}(\Omega)$  be a holomorphic function on  $\Omega$ . If  $|f|^2$  is a constant, show that  $f$  is constant as well.

**Proof.** Let  $f = u + \sqrt{-1}v$ , then  $|f|^2 = f\bar{f} = (u + \sqrt{-1}v)(u - \sqrt{-1}v) = u^2 + v^2 \equiv c$ . Since  $f \in \mathcal{O}(\Omega)$ , there holds Cauchy-Riemann equations  $\frac{\partial u}{\partial x^i} = \frac{\partial v}{\partial y^i} =: a_i$ ,  $-\frac{\partial u}{\partial y^i} = \frac{\partial v}{\partial x^i} =: b_i$  for  $i = 1, \dots, n$ . Take derivative to  $u^2 + v^2 \equiv c$  in the direction of  $x^i, y^i$  we have

$$\begin{cases} u \frac{\partial u}{\partial x^i} + v \frac{\partial v}{\partial x^i} = 0 \\ u \frac{\partial u}{\partial y^i} + v \frac{\partial v}{\partial y^i} = 0 \end{cases},$$

or,

$$\begin{cases} a_i u + b_i v = 0 \\ -b_i u + a_i v = 0 \end{cases}.$$

Solving the equations, we get either  $u = v = 0$ , which means  $f \equiv 0$  is constant, or  $a_i^2 + b_i^2 = 0$ , which means  $a_i = b_i = 0$ , leading to that  $u, v$  are constant, as well as  $f$ . This completes the proof.  $\square$

2. Let  $\phi, \psi : \mathcal{F} \rightarrow \mathcal{G}$  be morphisms of sheaves on a topological space  $\mathcal{X}$ . Show that if  $\phi_x = \psi_x$  as maps  $\mathcal{F}_x \rightarrow \mathcal{G}_x$  for all  $x \in \mathcal{X}$ , then  $\phi = \psi$  as morphisms of sheaves.

**Proof.** Without lose of generality, one can consider an open  $U \subset X$  and a section  $f \in \mathcal{F}(U)$ . Since  $[\phi(f)]_x = \phi_x(f_x) = \psi_x(f_x) = [\psi(f)]_x$  for all  $x \in U$ , where  $(-)_x : \mathcal{F}(U) \rightarrow \mathcal{F}_x, \mathcal{G}(U) \rightarrow \mathcal{G}_x$  denotes the natural map, by the definition of passing to the limit, there exists a subset  $x \in U_x \subset U$  such that  $\phi_{U_x}(f) = \psi_{U_x}(f)$  on  $\mathcal{G}(U_x)$ . Hence, by the first axiom of sheaf, due to the facts that  $U = \bigcup U_x$  as well as that  $r_{U_x}^U(\phi(f)) = r_{U_x}^U(\psi(f))$  by the compatibility of sheave morphism with restriction map, there holds  $\phi(f) = \psi(f)$  on  $\mathcal{G}(U)$ . Let  $f$  run over all the sections and  $U$  all the open subsets to complete the proof.  $\square$

3. Let  $X$  be a compact complex manifold. Let  $\mathcal{O}_X$  be the sheaf of holomorphic functions. Show that  $\mathcal{O}_X$  is not a soft sheaf.

**Proof.** We can choose suitable  $K$  to be closed and to be contained in a suitable chart  $(U, \varphi)$  such that  $0 \in \varphi(K)$ , then  $f \circ \varphi := \sum_{I \in \mathbb{N}^n} z^I$ , where  $I$  is a multiindex and  $n$  the

dimension of  $X$ , is clearly holomorphic on  $K' := K \cap \varphi^{-1}(\overline{B_{1/2}(0)})$ . It is well known, however, that a holomorphic function on a compact complex manifold must be a constant. Therefore  $f$  cannot be extended to a global holomorphic function on  $X$ , i.e. the restriction  $\mathcal{O}_X(X) \rightarrow \mathcal{O}_X(K')$  is not surjective, violating the definition of soft sheaf.  $\square$

4. Let  $X$  be a compact complex manifold of dimension  $n$ . Let  $L_1, \dots, L_n$  be holomorphic line bundles over  $X$ . Assume that  $L_1$  is trivial (i.e.  $L_1 \cong X \times \mathbb{C}$ ). Then show that the intersection number  $L_1 \bullet \dots \bullet L_n = 0$ .

**Proof.** From definition we have

$$L_1 \bullet \dots \bullet L_n = \frac{1}{(2\pi)^n} \int_X R_{h_1} \wedge \dots \wedge R_{h_n}$$

where  $R_h = -\sqrt{-1} \partial \bar{\partial} \log h$ . Obviously  $R_h$ 's are  $(1,1)$ -forms, therefore  $R_{h_1} \wedge \dots \wedge R_{h_n}$  exactly gives rise to a volume form. The triviality of  $L_1$  leads to a globally defined  $h_1$ , henceforth  $R_{h_1} = d(\frac{\partial - \bar{\partial}}{2\sqrt{-1}}(\log h_1))$  is d-exact. Applying Stokes' theorem the result is derived.  $\square$

5. Show that  $S^2 \times S^2$  admits a Kähler structure.

**Proof.** Since  $S^2 \cong \mathbb{CP}^1$ , we can consider  $\mathbb{CP}^1 \times \mathbb{CP}^1$  with Fubini-Study metric  $(\mathbb{CP}^1, \omega_{\text{FS}}) = (\mathbb{CP}^2, g, J)$ . We only need to check that the product of manifolds  $(X_1, g_1, J_1)$  and  $(X_2, g_2, J_2)$ , where  $X_1, X_2$  denote two  $\mathbb{CP}^1$  components, exactly give rise to a Kähler structure.

The product metric on  $(X = \mathbb{CP}^1 \times \mathbb{CP}^1, g_0, J_0)$  is given by  $g_0(u, v) = g_1(P_1 u, P_1 v) + g_2(P_2 u, P_2 v)$ . By letting  $J_0 = J_1 \oplus J_2$ , the product Kähler form given by  $\omega_0(u, v) = \omega_1(P_1 u, P_1 v) + \omega_2(P_2 u, P_2 v)$ , where  $P_{\pm}$  is the projective operator.

By simple calculation we derive  $\omega_0(u, u) = \omega_1(P_1 u, P_1 u) + \omega_2(P_2 u, P_2 u) > 0$  by the positive definiteness of  $\omega_1$  and  $\omega_2$ , meaning that  $\omega_0$  is also positive definite. Similarly from  $d\omega_0(u, v) = d\omega_1(P_1 u, P_1 v) + d\omega_2(P_2 u, P_2 v) = 0$  the d-closedness is also inherited to the product. Finally by the definition of admitting a Kähler structure, the proof is complete.  $\square$
